

Prob. RC Note

Chia-Cheng, Hao
Yan-Wei, Su

September 29, 2022

Abstract

This is a note for recitation in 2022 Fall undergraduate Probability Theory in the Applied Mathematics department at NYCU. The instructor of the course is Professor Yuan-Chung Sheu ([website](#)), and the two TA are Chia-Cheng, Hao and Yan-Wei, Su. The Github site for this note is at https://github.com/18Allen/PT_RC_material/blob/main/Notes/master.pdf

RC 0

Recitation 0

0.1 Basic rules

22 Sep. 18:30

- Recitation: Thursday 12:30 to 13:30, 18:30 to 19:30
- My office hour is right after recitation.
- Grade distribution: (quiz correction + attend rc): 1×4 ; mid correction + attend rc: 2; Attend one rc: 4

0.2 Review of some high school comminatory and probability tricks

Early chapters are about high school counting things over again. We will swiftly go through the concept.

0.2.1 Permutation and Combination

- Permutation
#ways to form an ordering of m out of n different things.

$$P(n, m)$$

- Combination
#ways to form a group of m with n different things.

$$C(n, m), \quad \binom{n}{m}$$

- Multinomial coefficents [Gra21]
#ways to divide a set of n elements into r (distinguishable) subsets of n_1, n_2, \dots, n_r elements.

$$\frac{n!}{n_1! n_2! \dots n_r!}$$

0.2.2 Set Operation

- De Morgan's Law

0.3 Axioms of Probability

0.3.1 Probability Space

The **probability space** is a triple Ω, \mathcal{F}, P that contains

- The **sample space** Ω contains all possible outcome.
- The σ -algebra \mathcal{F} is the **event space**. It is a subset of the power set of Ω we are interested in.
- The **probability measure** P is a function $P : \mathcal{F} \rightarrow [0, 1]$ that satisfies the three axioms.
 1. $P(\Omega) = 1$
 2. Non-negative
 3. Countable additivity for disjoint sets in \mathcal{F} .

0.3.2 Standard process

A standard process of solving these problems (HW1,2) is to find the size of possible outcome first. Then, finding the size of desired event, and the ratio of the two is the prob.

Example. [Gra21] Example 3.11

You have 10 pairs of socks in the closet. Pick 8 socks at random. For every i , compute the probability that you get i complete pairs of socks.

- # outcome:
- # desirable outcome:
- the probability is :

Example. [Gra21] Problem 3.2 (HW2 problem 2)

Three married couples take seats around a table at random. Compute $P(\text{no wife sits next to her husband})$. Use Inclusion-Exclusion principle to compute the probability of its complement event.

0.3.3 Why do we need to set σ -algebra: Vitali set

Have you ever wonder: Why would I need \mathcal{F} if I have Ω already? As the textbook said, you won't have any problem with this notion. However, things get messy when we encounter set of infinity size. The idea of "length" will not be clear then. We use **Vitali set** V as an example on \mathbb{R} to show that we can't have a measure on V . This problem is one of the reason that we only put probability measure on \mathcal{F} .

0.4 Homework Help

TBD

Chapter 1

RC 1

Recitation 1

1.1 Review

29 Sep. 18:30

1.1.1 Axioms of Probability

A **probability space** is a triple Ω, \mathcal{F}, P that contains

- The **sample space** Ω contains all possible outcome.
- The σ -algebra \mathcal{F} is the **event space**. It is a subset of the power set of Ω we are interested in.
- The **probability measure** P

1.1.2 Probability (measure)

- The **probability measure** P is a function $P : \mathcal{F} \rightarrow [0, 1]$ that satisfies the three axioms.
 1. $P(\Omega) = 1$
 2. Non-negative
 3. Countable additivity for disjoint sets in \mathcal{F} .

1.1.3 σ -algebra

\mathcal{F} is call a σ -algebra on a set Ω If

1. $\emptyset \in \mathcal{F}$
2. If $A \in \mathcal{F} \Rightarrow A^c \in \mathcal{F}$
3. If $A_1, A_2, \dots \in \mathcal{F}$, then $\cup_{i=1} A_i \in \mathcal{F}$

Example. Let $\Omega = \{1, 2, 3, 4, 5, 6\}$, find a minimal* σ -algebra that contains the sets $\{1, 2, 3\}, \{1\}$

Answer: ¹

1.1.4 Conditional Probability

For the general definition, take events A, B , and assume that $P(B) > 0$. The *conditional probability* of the event A given B equals

$$P(A|B) = \frac{P(A \cap B)}{P(B)}$$

TBD (an example)

¹ $\mathcal{F} = \{\emptyset, \Omega, \{1\}, \{1, 2, 3\}, \{4, 5, 6\}, \{2, 3, 4, 5, 6\}, \{2, 3\}, \{1, 4, 5, 6\}\}$

1.1.5 Independence

Events A_1, \dots, A_n are independent if

$$P(\cap_{i=1}^n A_i) = \prod_{i=1}^n P(A_i)$$

Please note that it means you can not just check $P(A_i \cap A_j) = P(A_i)P(A_j), i \neq j$. One example is the following

Example (Pairwise Independence but not independent variables). ([Pan19] Exercise 1.4.2) Consider a regular tetrahedron die painted blue, red and green on three sides and painted in all three colours on the fourth side. If the die is equally likely to land on any side, show that the appearances of these colours on the side it lands on are pairwise-independent but not independent.

1.2 Problems

Exercise. Put r distinguishable balls into n different boxes. What is the probability of all n boxes are occupied?

Probabilistic approach. $A_i = \{\text{Box } i \text{ is occupied}\}$ for all $i = 1, \dots, n$.

$$\mathbb{P}(\text{No empty boxes}) = \mathbb{P}\left(\bigcup_{i=1}^n A_i\right). \quad (1.1)$$

(Inclusion-exclusion principle!)

Combinatorial approach. Define $A(r, n)$ as the number of distributions such that all n boxes are non-empty when you put r balls into them. Then the probability is $A(r, n)/n^r$. Knowing $A(r, n+1)$ can lead us to $A(r, n)$:

$$A(r, n) = \sum_{k=1}^{r-1} \binom{r}{k} A(r-k, n-1). \quad (1.2)$$

Knowing this, we can prove that:

$$A(r, n) = \sum_{\nu=0}^n (-1)^\nu \binom{n}{\nu} (n-\nu)^r. \quad (1.3)$$

(Use Induction!)

(Think about it!) What is the probability of exactly m boxes are occupied?

$$\text{number of distributions} = \binom{n}{m} \times A(r, m). \quad (1.4)$$

$$A(r, m) = \mathbb{P}(r \text{ balls into } m \text{ boxes and all of the boxes are occupied}) \times m^r.$$

1. (Matching problem) There are a deck of N distinct cards and N distinct boxes. Shuffle the cards and placed them into the boxes (Only one card for each boxes), if the i -th card is placed at the i -th box, we say that there is a match. What is the probability of no match after a shuffling? Compute the limiting probability when $n \rightarrow \infty$.

2. (Matching problem, continuation) What is the probability of exactly m matches, $1 \leq m \leq n$?

3. (Example 3.13. from Gravner's note) Assume that 20 Scandinavians, 10 Finns and 10 Danes, are to be distributed at random into 10 rooms, 2 per room. What is the probability that exactly $2i$ rooms are mixed, $i = 0, \dots, 5$?

4. (c.f. Example 3.11. from Gravner's lecture note) You have n pairs of socks. If $2r$ socks was chosen randomly, what's the probability of getting exactly i pairs of socks?

Appendix

Appendix A

Additional Proofs

A.1 Proof of ??

We can now prove ??.

Proof of ??. See [here](#).
