## Q1

(c) ... size of the randomly chosen group. Let  $E[Y] = \mu$  and ...

## Partial solution to HW 6

### Q1

Checkout out chapter 5 Q5 solution in Janko Graver's book.

### Q2

(Panchenko Exercise 1.5.2) There could be many, my solution use shifted normalized Poisson Set discrete random variable  $X$ . We define the pmf  $f_X$  to be

$$f_X(x) \begin{cases} 1 - e^{-10}, & \text{if } x = 0; \\ e^{-10} e^{\lambda} \frac{\lambda^{(x-1)}}{(x-1)!}, & \text{if } x \in \mathbb{N}. \end{cases}$$

Then,  $P(X > 0) = e^{-10}$  is easy to check. Now we have to set the correct  $\lambda$ . By some calculation you can see that

$$\begin{aligned} E[X] &= \sum_{x=1}^{\infty} ((x-1) + 1) e^{-10} e^{\lambda} \frac{\lambda^{(x-1)}}{(x-1)!} \\ &= e^{-10} \underbrace{\sum_{x=0}^{\infty} x e^{\lambda} \frac{\lambda^x}{(x)!}}_{\text{expectation of Poisson}(\lambda)} + e^{-10} \\ &= e^{-10}(\lambda + 1) \end{aligned}$$

Hence, set  $\lambda = e^{10} - 1$  we will have  $E[X] = e^{10}$ .

□

### Q3

This is the same as the exercise in RC4 exercise for the indicator method. The number of pairs of animals alive,  $N$ , is not an easy random variable to compute. Therefore, we may consider "when will  $N$  increase?". This is easier,  $N$  increase 1 if a pair of animals is alive. Hence, the indicator we consider is  $1_{A_i}, i = 1, \dots, n$ , where  $A_i$  means the event that the  $i$ th pair of animal is alive.

$$\text{Then, we have } E[1_{A_i}] = P(A_i) = \binom{2(n-1)}{m} / \binom{2n}{m}$$

$$\begin{aligned} \text{Consequently, by linearity of expectation,} \\ E[N] = \sum_{i=1}^n E[1_{A_i}] = nP(A_1) = \frac{(2n-m)(2n-m-1)}{2(2n-1)} \text{ pairs.} \end{aligned}$$

□

**Q4**

Again, this is a problem using the indicator method. The probability that geese  $i$  ( $i = 1, \dots, 6$ ) will be dead is TBD

**Q5****Q6**

- (a) Calculate  $E[X^2] = p$ , and use  $\text{Var}(X) = E[X^2] - E[X]^2$ .
- (b) We did that in recitation class. If you forget, try to use the method introduced in handout Chapter 3 page 14 of from prof. Sheu.
- (c) Recall that  $E[aX + b] = aE[X] + b$  due to the linearity of expectation. We have  $\text{Var}(aX + b) = E[(aX + b - (aE[X] + b))^2] = E[a^2(X - E[X])^2] = a^2\text{Var}(X)$

**Q7**

First, we can eyeball  $E[Y] = 0$  because  $(X_i)_{i=1}^n$  are i.i.d and we have  $E[X_i] = 0$ . Hence, what is left is to calculate  $E[Y^2]$ . Before we dive in to calculation, again we have to observe which terms will not be zero? Those with first order  $X_i$  will be zero, e.g.  $E[X_1^2 X_2 X_3], E[X_1 X_2 X_3 X_4]$  are zero. Hence, we only have to consider terms like  $E[X_1^2 X_2^2]$  that have only second order moment. Also  $E[X_i^2 X_j^2] = 1$ , for any  $1 \leq i < j \leq n$ .

$$E[Y^2] = \sum_{k < l} \sum_{i < j} E[X_i X_j X_k X_l] = \sum_{i < j} E[X_i^2 X_j^2] = \frac{n(n-1)}{2} \cdot E[X_1^2 X_2^2] = \frac{n(n-1)}{2}$$

□

**Q8**

Check out Chapter 3 handout page 14 by prof. Sheu.

**Q9**

This is a problem using the fact that  $E[XY] = E[X]E[Y]$  if  $X, Y$  are independent.

- $E[XY] = E[X]E[Y]$  if  $X, Y$  are independent.

$$\text{Var}(X_1 X_2) = E[(X_1 X_2 - E[X_1 X_2])^2] = E[(X_1 X_2 - E[X_1]E[X_2])^2]$$
